

<b>Name: VINCENT BRYAN BOSE</b>	<b>Date Performed: 26-9-2024</b>
<b>Course/Section: CPE31S2</b>	<b>Date Submitted: 26-9-2024</b>
<b>Instructor: Engr. Robin Valenzuela</b>	<b>Semester and SY: 1st sem 2024-2025</b>
<b>Activity 5: Consolidating Playbook plays</b>	
<b>1. Objectives:</b> 1.1 Use <b>when</b> command in playbook for different OS distributions 1.2 Apply refactoring techniques in cleaning up the playbook codes	
<b>2. Discussion:</b>  <p>We are going to look at a way that we can differentiate a playbook by a host in terms of which distribution the host is running. It's very common in most Linux shops to run multiple distributions, for example, Ubuntu shop or Debian shop and you need a different distribution for a one off-case or perhaps you want to run plays only on certain distributions.</p> <p>It is a best practice in ansible when you are working in a collaborative environment to use the command git pull. git pull is a Git command used to update the local version of a repository from a remote. By default, git pull does two things. Updates the current local working branch (currently checked out branch) and updates the remote-tracking branches for all other branches. git pull essentially pulls down any changes that may have happened since the last time you worked on the repository.</p> <p><b>Requirement:</b>  In this activity, you will need to create a CentOS VM. Likewise, you need to activate the second adapter to a host-only adapter after the installations. Take note of the IP address of the CentOS VM. Make sure to use the command <b>ssh-copy-id</b> to copy the public key to CentOS. Verify if you can successfully SSH to CentOS VM.</p>	
<b>Task 1: Use when command for different distributions</b>  1. In the local machine, make sure you are in the local repository directory ( <b>CPE232_yourname</b> ). Issue the command git pull. When prompted, enter the correct passphrase or password. Describe what happened when you issue this	

command. Did something happen? Why?

```

```

2. Edit the inventory file and add the IP address of the Centos VM. Issue the command we used to execute the playbook (the one we used in the last activity): `ansible-playbook --ask-become-pass install_apache.yml`. After executing this command, you may notice that it did not become successful in the Centos VM. You can see that the Centos VM has failed=1. Only the two remote servers have been changed. The reason is that Centos VM does not support "apt" as the package manager. The default package manager for Centos is "yum."

```

vbbose@workstation:~/Bose-HOA-5.1$
```

- Since we code the condition to perform the job when the node's OS is Ubuntu, it bypasses the CentOS Manage Node and proceeds directly to the task.

If you have a mix of Debian and Ubuntu servers, you can change the configuration of your playbook like this.

- name: update repository index  
apt:  
  update\_cache: yes  
  when: ansible\_distribution in ["Debian", "Ubuntu"]

Note: This will work also if you try. Notice the changes are highlighted.

4. Edit the *install\_apache.yml* file and insert the lines shown below.

```
---
- hosts: all
  become: true
  tasks:

    - name: update repository index
      apt:
        update_cache: yes
      when: ansible_distribution == "Ubuntu"

    - name: install apache2 package
      apt:
        name: apache2
        state: latest
      when: ansible_distribution == "Ubuntu"

    - name: add PHP support for apache
      apt:
        name: libapache2-mod-php
        state: latest
      when: ansible_distribution == "Ubuntu"

    - name: update repository index
      dnf:
        update_cache: yes
      when: ansible_distribution == "CentOS"

    - name: install apache2 package
      dnf:
        name: httpd
        state: latest
      when: ansible_distribution == "CentOS"

```

- It completes each task individually in accordance with the OS's designated condition.

5. To verify the installations, go to CentOS VM and type its IP address on the browser. Was it successful? The answer is no. It's because the httpd service or the Apache HTTP server in the CentOS is not yet active. Thus, you need to activate it first.

5.1 To activate, go to the CentOS VM terminal and enter the following:

*systemctl status httpd*

The result of this command tells you that the service is inactive.

5.2 Issue the following command to start the service:

*sudo systemctl start httpd*

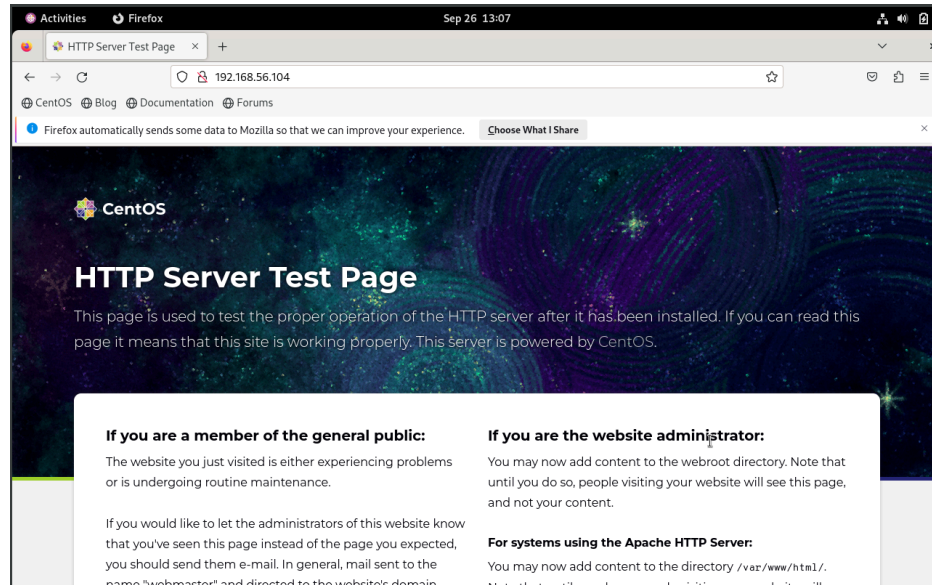

(When prompted, enter the sudo password)

*sudo firewall-cmd --add-port=80/tcp*

(The result should be a success)

5.3 To verify the service is already running, go to CentOS VM and type its IP address on the browser. Was it successful? (Screenshot the browser)

## Task 2: Refactoring playbook

This time, we want to make sure that our playbook is efficient and that the codes are easier to read. This will also makes run ansible more quickly if it has to execute fewer tasks to do the same thing.

1. Edit the playbook *install\_apache.yml*. Currently, we have three tasks targeting our Ubuntu machines and 3 tasks targeting our CentOS machine. Right now, we try to consolidate some tasks that are typically the same. For example, we can consolidate two plays that install packages. We can do that by creating a list of installation packages as shown below:

```

---
- hosts: all
  become: true
  tasks:

    - name: update repository index Ubuntu
      apt:
        update_cache: yes
        when: ansible_distribution == "Ubuntu"

    - name: install apache2 and php packages for Ubuntu
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        when: ansible_distribution == "Ubuntu"

    - name: update repository index for CentOS
      dnf:
        update_cache: yes
        when: ansible_distribution == "CentOS"

    - name: install apache and php packages for CentOS
      dnf:
        name:
          - httpd
          - php
        state: latest
        when: ansible_distribution == "CentOS"

```

Make sure to save the file and exit.

```
vbb@workstation: ~/Bose-HOA-5.1
GNU nano 6.2 install_apache.yml *
tasks:
  - name: update repository index Ubuntu
    apt:
      update_cache: yes
      when: ansible_distribution == "Ubuntu"
  - name: install apache2 and php packages for Ubuntu
    apt:
      name:
        - apache2
        - libapache2-mod-php
      state: latest
      when: ansible_distribution == "Ubuntu"
  - name: update repository index CentOS
    dnf:
      update_cache: yes
      when: ansible_distribution == "CentOS"
  - name: install apache2 and php packages for CentOS
    dnf:
      name: httpd
      state: latest
      when: ansible_distribution == "CentOS"
  - name: add PHP support for apache
    dnf:
      name:
        - httpd
        - php
      state: latest
      when: ansible_distribution == "CentOS"

vbb@workstation:~/Bose-HOA-5.1$ s
```

- The same task, but with the code simplified, it was completed considerably more rapidly.

2. Edit the playbook *install\_apache.yml* again. In task 2.1, we consolidated the plays into one play. This time we can actually consolidated everything in just 2 plays. This can be done by removing the update repository play and putting the command *update\_cache: yes* below the command *state: latest*. See below for reference:

```
---
- hosts: all
  become: true
  tasks:

    - name: install apache2 and php packages for Ubuntu
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        update_cache: yes
      when: ansible_distribution == "Ubuntu"

    - name: install apache and php packages for CentOS
      dnf:
        name:
          - httpd
          - php
        state: latest
        update_cache: yes
      when: ansible_distribution == "CentOS"
```

Make sure to save the file and exit.

```
vbbose@workstation: ~/E
GNU nano 6.2 install_apac
---
- hosts: all
  become: true
  tasks:
    - name: install apache2 and php packages for Ubuntu
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        update_cache: yes
        when: ansible_distribution == "Ubuntu"
    - name: install apache2 and php packages for CentOS
      dnf:
        name: httpd
        state: latest
        update_cache: yes
        when: ansible_distribution == "CentOS"
```

Run *ansible-playbook --ask-become-pass install\_apache.yml* and describe the result.

```

- Now that the task is divided into two categories, the code is easier to read and more straightforward.

- Finally, we can consolidate these 2 plays in just 1 play. This can be done by declaring variables that will represent the packages that we want to install. Basically, the `apache_package` and `php_package` are variables. The names are arbitrary, which means we can choose different names. We also take out the line when: `ansible_distribution`. Edit the playbook *install\_apache.yml* again and make sure to follow the below image. Make sure to save the file and exit.

```

---
- hosts: all
  become: true
  tasks:

    - name: install apache and php
      apt:
        name:
          - "{{ apache_package }}"
          - "{{ php_package }}"
        state: latest
        update_cache: yes

```

```
GNU nano 6.2
---
- hosts: all
  become: true
  tasks:
    - name: install apache and php
      apt:
        name:
          - "{{ apache_package }}"
          - "{{ php_package }}"
        state: latest
        update_cache: yes
```

Run *ansible-playbook --ask-become-pass install\_apache.yml* and describe the result.

```

- It didn't work; I think it was merely a variable that indicated the input wasn't exactly meaningful.

4. Unfortunately, task 2.3 was not successful. It's because we need to change something in the inventory file so that the variables we declared will be in place. Edit the *inventory* file and follow the below configuration:

```
192.168.56.120 apache_package=apache2 php_package=libapache2-mod-php
192.168.56.121 apache_package=apache2 php_package=libapache2-mod-php
192.168.56.122 apache_package=httpd php_package=php
```

Make sure to save the *inventory* file and exit.

```
vbbose@workstation: ~/Bose-HOA-5.1
GNU nano 6.2 inventory *
[servers]
192.168.56.102 apache_package=apache2 php_package=libapache2-mod-php

[CentOS]
192.168.56.104 ansible_user=vbbose apache_package=httpd php_package=php
```

**Finally**, we still have one more thing to change in our *install\_apache.yml* file. In task 2.3, you may notice that the package is assign as *apt*, which will not run in CentOS. Replace the *apt* with *package*. *Package* is a module in ansible that is generic, which is going to use whatever package manager the underlying host or the target server uses. For Ubuntu it will automatically use *apt*, and for CentOS it will automatically use *dnf*. Make sure to save the file and exit. For more details about the ansible package, you may refer to this documentation: [ansible.builtin.package – Generic OS package manager — Ansible Documentation](#)

```
vbbose@workstation: ~/Bose-HOA
GNU nano 6.2 install_apache.yml *
---
- hosts: all
  become: true
  tasks:
  - name: install apache and php
    package:
      name:
        - "{{ apache_package }}"
        - "{{ php_package }}"
      state: latest
      update_cache: yes
```

Run *ansible-playbook --ask-become-pass install\_apache.yml* and describe the result.

```
ybb@workstation:~/Bose-HOA-5.1$ ansible-playbook --ask-become-pass install_apache.yml
BECOME password:

PLAY [all] *****

TASK [Gathering Facts] *****
ok: [192.168.56.102]
ok: [192.168.56.104]

TASK [install apache and php] *****
ok: [192.168.56.102]
ok: [192.168.56.104]

PLAY RECAP *****
192.168.56.102      : ok=2    changed=0    unreachable=0    failed=0    skipped=0    rescued=0    ignored=0
192.168.56.104      : ok=2    changed=0    unreachable=0    failed=0    skipped=0    rescued=0    ignored=0
```

- **Because every task is completed using the smallest syntax feasible, the outputs are far cleaner than they were.**

### Reflections:

Answer the following:

1. Why do you think refactoring of playbook codes is important?
  - For the purpose of streamlining and optimizing Ansible's task execution. There are other tasks to be completed, as the images above illustrate, including verifying the distribution used by the manage nodes and vice versa. The playbook's runtime is significantly faster than the lengthy syntax playbook when the code is simplified.
2. When do we use the "when" command in playbook?
  - When managing nodes with various distributions. Because CentOS has a distinct syntax for package installation, we utilize when in the activity to divide the package installations. Since we set up a variable in the playbook and modify the inventory to set it up, we utilize a package. Then, to automatically set up the package installation without requiring you to switch between apt for Ubuntu and dnf for CentOS, we use packages in place of apt.
